

STELLAR COLLAPSE IN THE TIME DEPENDENT HARTREE-FOCK APPROXIMATION

CHRISTIAN HAINZL AND BENJAMIN SCHLEIN

ABSTRACT. We prove blow-up in finite time for radially symmetric solutions to the pseudo-relativistic Hartree-Fock equation with negative energy. The non-linear Hartree-Fock equation is commonly used in the physics literature to describe the dynamics of white dwarfs. We extend thereby recent results by Fröhlich and Lenzmann, who established in [3, 4] blow-up for solutions to the pseudo-relativistic Hartree equation. As key ingredient for handling the exchange term we use the conservation of the expectation of the square of the angular momentum operator.

1. INTRODUCTION

According to the theory of Chandrasekhar [1], white dwarfs can be described by a model of electrically neutral atoms interacting through classical Newtonian gravitation. Atoms consist of nuclei, which are responsible for the main part of the potential energy, and electrons, which, on the other hand, give the leading contribution to the kinetic energy of the star. Because of local charge neutrality, we can assume that the space and momentum distributions of the nuclei coincide with the ones of the electrons; in this approximation, we only keep track of the electronic degrees of freedom. Considering a relativistic dispersion $E(p) = \sqrt{p^2 + m^2}$ for electrons with mass m , and assuming a single species of nuclei with mass $m_Z \gg m$ and charge Ze (where $-e$ denotes the charge of the electron), this simplified model is described, on the microscopic level, by the quantum mechanical Hamiltonian

$$(1.1) \quad H_N = \sum_{j=1}^N \sqrt{-\Delta_{x_j} + m^2} - \kappa \sum_{i < j}^N \frac{1}{|x_i - x_j|}$$

where N is the number of electrons and $\kappa = Gm_Z^2/Z^2$ (G denotes here the gravitational constant). We use units with $\hbar = c = 1$.

Since the electron spin does not play an important role, we neglect it, and describe electrons by wave functions in $L^2(\mathbb{R}^3)$. In accordance with Pauli's principle, the Hamiltonian (1.1) acts then on the antisymmetric tensor product space $\mathcal{H}_N = \bigwedge^N L^2(\mathbb{R}^3, dx)$.

In [5, 6] Lieb and Yau derived Chandrasekhar equation for the ground state of the Hamiltonian (1.1) in the limit of large N with $\kappa N^{2/3}$ kept fixed. Additionally they reproduced Chandrasekhar critical number of particles $N_c \sim O(\kappa^{-3/2})$ proving the instability of (1.1) for all $N > N_c$ (the white dwarf is supposed to undergo gravitational collapse for $N > N_c$). Up to a factor 4 the correct value of N_c had already been established by Lieb and Thirring in [7]. See [5, 6, 7, 4] for a more thorough discussion on white dwarfs. In principle (1.1) can also be used to describe

neutron stars; however, in this case, a correct understanding of the collapse requires the inclusion of general relativity effects.

In the physical relevant regime of very small κ and very large N , one expects the ground state of (1.1) to be approximated by a Slater determinant

$$(\psi_1 \wedge \psi_2 \wedge \cdots \wedge \psi_N)(\mathbf{x}) = \frac{1}{\sqrt{N!}} \sum_{\pi \in S_N} \sigma_\pi \psi_1(x_{\pi 1}) \psi_2(x_{\pi 2}) \cdots \psi_N(x_{\pi N})$$

of N orthonormal one-particle wave functions $\psi_j \in L^2(\mathbb{R}^3)$ (here the sum runs over all permutations of the N particles; moreover, $\sigma_\pi = 1$ if the permutation π is even while $\sigma_\pi = -1$ if it is odd). It is simple to verify that the energy of the Slater determinant $\wedge_{j=1}^N \psi_j$ is given by the so called Hartree-Fock functional

(1.2)

$$\begin{aligned} \mathcal{E}_{\text{HF}}(\{\psi_j\}_{j=1}^N) &= \sum_{j=1}^N \int dx |(-\Delta + m^2)^{1/2} \psi_j(x)|^2 \\ &\quad - \frac{\kappa}{2} \sum_{i,j=1}^N \int dx dy \frac{|\psi_i(x)|^2 |\psi_j(y)|^2 - \psi_i(x) \bar{\psi}_i(y) \psi_j(y) \bar{\psi}_j(x)}{|x - y|}. \end{aligned}$$

Within the range of its applicability, one also expects the Hartree-Fock theory to describe the time-evolution of Slater determinants. In other words, one expects that, in an appropriate sense, and in a suitable limit of large N and small κ ,

$$e^{-iH_N t} (\psi_1 \wedge \cdots \wedge \psi_N) \simeq \psi_1(t) \wedge \psi_2(t) \wedge \cdots \wedge \psi_N(t)$$

where the wave functions evolve according to the time-dependent Hartree-Fock equation

$$(1.3) \quad i\partial_t \psi_j = \sqrt{-\Delta + m^2} \psi_j - \kappa \sum_{i=1}^N \left(\frac{1}{|\cdot|} * |\psi_i|^2 \right) \psi_j + \kappa \sum_{i=1}^N \left(\frac{1}{|\cdot|} * \psi_j \bar{\psi}_i \right) \psi_i.$$

Note that this system of non-linear equations, which can be formally obtained computing the variation of (1.2), preserves the orthonormality relations $\langle \psi_i(t), \psi_j(t) \rangle = \delta_{ij}$ and the energy \mathcal{E}_{HF} .

The Hartree-Fock theory can be formulated in a more compact form in terms of the orthogonal projection $Q = \sum_{j=1}^N |\psi_j\rangle \langle \psi_j|$ onto the subspace spanned by the wave functions $\{\psi_j\}_{j=1}^N$. The Hartree-Fock energy (1.2) is given, in terms of Q and its kernel $Q(x, y)$, by

$$(1.4) \quad \mathcal{E}_{\text{HF}}(Q) = \text{tr} \sqrt{-\Delta + m^2} Q - \frac{\kappa}{2} \int dx dy \frac{Q(x, x)Q(y, y) - |Q(x, y)|^2}{|x - y|}.$$

Also the time-dependent Hartree-Fock system (1.3) can be translated into an evolution equation for the time dependent density $Q_t = \sum_{j=1}^N |\psi_j(t)\rangle \langle \psi_j(t)|$. It is easy to obtain the nonlinear Hartree-Fock equation

$$(1.5) \quad i\partial_t Q_t = \left[(-\Delta + m^2)^{1/2} - \kappa \left(\frac{1}{|\cdot|} * \rho_{Q_t} \right) + \kappa R_{Q_t}, Q_t \right],$$

where $\rho_{Q_t}(x) = Q_t(x, x)$ (we denote by $Q_t(x, y)$ the kernel of the projection Q), and where the operator R_{Q_t} is defined by its kernel $R_{Q_t}(x, y) = Q_t(x, y)/|x - y|$. By construction, it is clear that (1.5) preserves the trace $N = \text{tr} Q_t$, and the

energy (1.4). In the present paper we are interested in solutions to the nonlinear Hartree-Fock equation (1.5); in particular we prove the existence of solutions to (1.5) which exhibit blow up in finite time. Within the framework of the Hartree-Fock approximation, the blow up of solutions to (1.5) is interpreted as evidence for the dynamical collapse of white dwarfs.

The last contribution in the commutator on the r.h.s. of (1.5) (the term containing the operator R_Q) is known as the exchange term (while the second contribution, containing the density ρ_Q , is known as the direct term). The presence of the exchange term is a consequence of the Pauli principle. Since, in the relevant limit of large N and small κ , the exchange term is expected to be of smaller order compared with the direct term, it is often neglected in the physics literature. In this approximation one obtains the Hartree equation

$$(1.6) \quad i\partial_t Q_t = \left[(-\Delta + m^2)^{1/2} - \kappa \left(\frac{1}{|\cdot|} * \rho_{Q_t} \right), Q_t \right].$$

For bosonic systems (boson stars) this equation has been in fact rigorously derived from many body quantum dynamics in [2].

Recently, blow-up in finite time has been proven to occur for solutions to the Hartree equation (1.6) by Fröhlich and Lenzmann in [3, 4]. To obtain this result, they consider the non-negative observable

$$M = x\sqrt{-\Delta + m^2}x = \sum_{j=1}^3 x_j \sqrt{-\Delta + m^2} x_j$$

and they estimate the expectation value $\text{tr}(MQ_t)$ where Q_t is a solution to (1.6) with spherical symmetry (in the sense that $Q_t(Rx, Ry) = Q_t(x, y)$ for all $R \in SO(3)$). Under this assumption, they show that

$$(1.7) \quad \text{tr} MQ_t \leq 2t^2 \mathcal{E}_{\text{Hartree}}(Q) + O(t)$$

where $O(t)$ denotes error terms growing at most linearly in t . For initial data with negative energy $\mathcal{E}_{\text{Hartree}}(Q) < 0$, Eq. (1.7) leads to a contradiction to the non-negativity of the observable M (choosing t sufficiently large). This implies that the solution Q_t cannot exist globally in time.

The spherical symmetry of the density Q plays a very important role in the analysis developed by Fröhlich and Lenzmann; it allows them to control error terms arising from the commutator of M with the interaction $(|\cdot|^{-1} * \rho_{Q_t})$ (the time derivative of $\text{tr} MQ_t$ contains the term $\text{tr} [M, (|\cdot|^{-1} * \rho_{Q_t})]Q_t$). The same approach can be applied to solutions of the Hartree-Fock equation (1.5); it turns out, however, that the error terms arising from the commutator of M with the exchange term R_Q cannot be handled like the errors arising from the direct term. This is the reason why the approach of Fröhlich and Lenzmann does not extend in a simple way to the Hartree-Fock equation (1.5) (the method does extend to the Hartree-Fock equation if one assumes not only that Q is spherically symmetric, but also that each orbital in its decomposition $Q = \sum_{j=1}^N |\psi_j\rangle\langle\psi_j|$ is spherically symmetric; however, as pointed out in [4], this is a physically unnatural condition).

In our analysis, we use the strategy of Fröhlich and Lenzmann; we study the evolution of the observable $M = x\sqrt{-\Delta + m^2}x$ on spherically symmetric solutions Q_t of (1.5) and we obtain a bound like (1.7). The novelty of our approach lies in the estimate of the error terms arising from the commutator of M with the exchange

term R_Q ; to control this error terms, we make use of the expectation of the square of the angular momentum operator, which is a conserved quantity due to the radial symmetry.

2. THE MAIN RESULT AND ITS PROOF

The local well-posedness of the Hartree-Fock system (1.3) has been established by Fröhlich and Lenzmann in [4, Theorem 1]. The well-posedness of (1.5) follows along the same line. For $s \geq 0$ we define the space

$$\mathcal{H}_s = \{Q \in \mathcal{L}^1(L^2(\mathbb{R}^3)) : \|Q\|_{\mathcal{H}_s} < \infty\}$$

with the norm

$$\|Q\|_{\mathcal{H}_s} = \text{tr} \left| (1 - \Delta)^{s/2} Q (1 - \Delta)^{s/2} \right|.$$

It turns out that (1.5) is locally well-posed in \mathcal{H}_s for all $s \geq 1/2$.

Theorem 1 (Local Well-Posedness, [4]). *Fix $s \geq 1/2$. For every orthogonal projection $Q \in \mathcal{H}_s(L^2(\mathbb{R}^3))$ with $N(Q) = \text{tr } Q < \infty$ there exists a maximal existence time $T > 0$ and a unique solution $Q_t \in C([0, T], \mathcal{H}^s(L^2(\mathbb{R}^3)))$ of (1.5) with $Q_t \geq 0$, and $\text{tr } Q_t = N$ for all $t \in [0, T)$. Moreover, if $T < \infty$, then $\|Q_t\|_s = \text{tr}(1 - \Delta)^s Q_t \rightarrow \infty$ as $t \rightarrow T^-$ (blow-up alternative).*

For sufficiently small values of $N = \text{tr } Q$, Fröhlich and Lenzmann also proved global well-posedness of the Hartree-Fock equation in [4, Theorem 2]. Our goal here is to prove that, for sufficiently large values of $N = \text{tr } Q$, blow up in finite time can occur. In particular, we show that the time evolution of an arbitrary spherically symmetric density with negative energy and with finite expectation for the square of the angular momentum operator exhibits blow-up in finite time. To prove this result, we need a few simple preliminary lemmas. First of all, we need to prove that the spherical symmetry is preserved by the time-evolution; this follows easily from the local uniqueness of the solution to (1.5).

Lemma 2.1. *Let $Q \in \mathcal{H}^{1/2}(L^2(\mathbb{R}^3))$, $Q \geq 0$, and assume that Q is spherically symmetric in the sense that*

$$Q(Rx, Ry) = Q(x, y) \quad \text{for all } R \in SO(3).$$

For $t \in [0, T)$ denote by Q_t the local in time solution to (1.5) with $Q_{t=0} = Q$. Then, for every $t \in [0, T)$, we have

$$(2.1) \quad Q_t(Rx, Ry) = Q_t(x, y) \quad \text{for all } R \in SO(3).$$

Proof. For arbitrary $R \in SO(3)$, we define $\tilde{Q}_t(x, y) = Q_t(Rx, Ry)$. It is then simple to verify that \tilde{Q}_t is also a solution to (1.5), characterized by the same initial data. By the local uniqueness of the solution, we immediately obtain (2.1). \square

The main reason why spherical symmetry is so important to prove the blow up of solutions of (1.5) is Newton's Law, as stated in the following lemma.

Lemma 2.2 (Newton's Law). *Suppose that $\rho \in L^1(\mathbb{R}^3, dx)$ is spherical symmetric with $N = \int dy \rho(y)$. Then*

$$(2.2) \quad \int dy \frac{\rho(y)}{|x - y|} \leq \frac{N}{|x|} \quad \text{and} \quad \left| \nabla_x \int dy \frac{\rho(y)}{|x - y|} \right| \leq \frac{N}{|x|^2}$$

for a.e. $x \in \mathbb{R}^3$.

Proof. The proof relies on the explicit formula for radial functions

$$\int dy \frac{\rho(y)}{|x-y|} = \frac{1}{|x|} \int_{|y| \leq |x|} dy \rho(y) + \int_{|y| > |x|} dy \frac{\rho(y)}{|y|}.$$

For $\rho \in L^1(\mathbb{R}^3) \cap C^0(\mathbb{R}^3)$, explicit differentiation leads to

$$\left| \nabla_x \int dy \frac{\rho(y)}{|x-y|} \right| = \frac{1}{|x|^2} \int_{|y| \leq |x|} dy \rho(y) \leq \frac{N}{|x|^2}.$$

For general spherical symmetric $\rho \in L^1(\mathbb{R}^3)$ the statement follows using a simple density argument. \square

An important tool in the proof of the finite time blow-up of solutions of (1.5) is the fact that the expectation of the square of the angular momentum operator $L = x \wedge p$ is preserved by the time evolution thanks to spherically symmetric solutions.

Lemma 2.3. *Let $L = x \wedge p$ denote the angular momentum operator. Let $Q \in \mathcal{H}^{1/2}(L^2(\mathbb{R}^3))$, $Q \geq 0$ be a spherical symmetric density with*

$$\text{tr } L^2 Q < \infty.$$

For $t \in [0, T)$, denote by Q_t the local in time solution of (1.5) with $Q_{t=0} = Q$. Then

$$\text{tr } L^2 Q_t = \text{tr } L^2 Q \quad \text{for all } t \in [0, T).$$

Proof. Observe that the angular momentum operator L generates rotations in the sense that

$$(e^{iL \cdot \alpha} \psi)(x) = \psi(R_\alpha x)$$

for all $\psi \in L^2(\mathbb{R}^3)$. Here $R_\alpha \in SO(3)$ denotes the rotation around the axis $\hat{\alpha}$, with angle $|\alpha|$. This implies that, for an arbitrary spherical symmetric density Q , we have

$$(e^{iL \cdot \alpha} Q e^{-iL \cdot \alpha})(x, y) = Q(R_\alpha x, R_\alpha y) = Q(x, y)$$

for all α . Differentiating with respect to α , we obtain that $[L, Q] = 0$ and thus that $[L^2, Q] = 0$ for any spherically symmetric density Q . Now, since the time evolution Q_t of the spherical symmetric initial data Q is spherical symmetric (by Lemma 2.1), it follows that

$$\begin{aligned} \frac{d}{dt} \text{tr } L^2 Q_t &= \text{tr } L^2 \left[\sqrt{p^2 + m^2} - \kappa \left(\frac{1}{|\cdot|} * \rho_{Q_t} \right) + \kappa R_{Q_t}, Q_t \right] \\ &= \text{tr} \left(\sqrt{p^2 + m^2} - \kappa \left(\frac{1}{|\cdot|} * \rho_{Q_t} \right) + \kappa R_{Q_t} \right) [Q_t, L^2] = 0. \end{aligned}$$

\square

We are now ready to state and prove our main theorem.

Theorem 2. *(Blow-up for Hartree-Fock) Let $Q \in \mathcal{H}^{1/2}(L^2(\mathbb{R}^3))$ be a spherical symmetric orthogonal projection with $N(Q) = \text{tr } Q < \infty$, with negative energy $\mathcal{E}_{HF}(Q) < 0$, with finite expectation of the square of the angular momentum operator $\mathcal{L}^2(Q) = \text{tr } L^2 Q < \infty$, such that*

$$(2.3) \quad \text{tr } x^4 Q < \infty, \quad \text{and} \quad \text{tr } (-\Delta) Q < \infty.$$

For $t \in [0, T)$, let Q_t denote the maximal local in time solution to (1.5) with $Q_{t=0} = Q$. Then $T < \infty$ and

$$\|Q_t\|_{H^{1/2}}^2 = \text{tr} (1 - \Delta)^{1/2} Q_t \rightarrow \infty \quad \text{as } t \rightarrow T^-.$$

Remarks.

- According to [4, Theorem 4] our main Theorem 2 implies that when approaching the time of blow-up any blow-up solution exhibits a concentration of particles at the origin, with

$$\lim_{t \rightarrow T^-} \inf_{|x| \leq R} \int dx \rho_{Q_t}(x) > 0 \quad \text{for any } R > 0.$$

- The condition $\mathcal{E}_{\text{HF}}(Q) < 0$ requires $N = \text{tr} Q$ to be sufficiently large.

Proof. Throughout the proof, we will use the notation $p = -i\nabla_x$. Consider the observable $M = x\sqrt{p^2 + m^2}x = \sum_{j=1}^3 x_j \sqrt{p^2 + m^2} x_j$. We are interested in the time evolution of the expectation $\text{tr}(MQ_t)$.

Step 1. There exists a constant C , only depending on $N(Q)$ and $\mathcal{L}^2(Q)$, such that

$$(2.4) \quad \frac{d}{dt} \text{tr} MQ_t \leq \text{tr} (p \cdot x + x \cdot p) Q_t + C.$$

To prove (2.4) we start by computing

$$(2.5) \quad \begin{aligned} \frac{d}{dt} \text{tr} MQ_t &= -i \text{tr} M \left[\sqrt{p^2 + m^2} - \kappa \left(\frac{1}{|\cdot|} * \rho_{Q_t} \right) + \kappa R_{Q_t}, Q_t \right] \\ &= -i \text{tr} \left[x\sqrt{p^2 + m^2}x, \sqrt{p^2 + m^2} \right] Q_t \\ &\quad + i\kappa \text{tr} \left[x\sqrt{p^2 + m^2}x, \left(\frac{1}{|\cdot|} * \rho_{Q_t} \right) \right] Q_t \\ &\quad - i\kappa \text{tr} \left[x\sqrt{p^2 + m^2}x, R_{Q_t} \right] Q_t. \end{aligned}$$

Using that $x = i\nabla_p$, the first term on the r.h.s. of the last equation is given by

$$-i \text{tr} \left[x\sqrt{p^2 + m^2}x, \sqrt{p^2 + m^2} \right] Q_t = \text{tr} (p \cdot x + x \cdot p) Q_t.$$

To control the second term on the r.h.s. of (2.5), let $V_{Q_t}(x) = (|\cdot|^{-1} * \rho_{Q_t})(x)$. Then

$$\begin{aligned} i\kappa \text{tr} \left[x\sqrt{p^2 + m^2}x, V_{Q_t} \right] Q_t &= i\kappa \text{tr} \left(x\sqrt{p^2 + m^2}x V_{Q_t}(x) - V_{Q_t}(x) x\sqrt{p^2 + m^2}x \right) Q_t \\ &= i\kappa \text{tr} \left[\sqrt{p^2 + m^2}, x^2 V_{Q_t}(x) \right] Q_t \\ &\quad - \kappa \text{tr} \left(\frac{p}{\sqrt{p^2 + m^2}} \cdot x V_{Q_t}(x) + V_{Q_t}(x) x \cdot \frac{p}{\sqrt{p^2 + m^2}} \right) Q_t. \end{aligned}$$

Therefore, using Lemma 2.4, we find

$$(2.6) \quad \begin{aligned} \left| i\kappa \text{tr} \left[x\sqrt{p^2 + m^2}x, V_{Q_t} \right] Q_t \right| &\leq \kappa N \left\| \left[\sqrt{p^2 + m^2}, x^2 V_{Q_t}(x) \right] \right\| + \kappa N \|x V_{Q_t}(x)\| \\ &\leq \kappa N (\|x V_{Q_t}(x)\| + \|x^2 \nabla V_{Q_t}\|). \end{aligned}$$

By Newton's law (Lemma 2.2), we have

$$(2.7) \quad \|xV_{Q_t}\| = \sup_{x \in \mathbb{R}^3} |x| \int dy \frac{\rho_{Q_t}(y)}{|x-y|} \leq CN$$

and

$$(2.8) \quad \|x^2 \nabla V_{Q_t}\| = \sup_{x \in \mathbb{R}^3} |x|^2 \left| \nabla_x \int dy \frac{\rho_{Q_t}(y)}{|x-y|} \right| \leq CN.$$

From (2.6), it follows that the second term on the r.h.s. of (2.5) is bounded, in absolute value, by

$$(2.9) \quad \left| i\kappa \operatorname{tr} \left[x\sqrt{p^2 + m^2} x, V_{Q_t} \right] Q_t \right| \leq C\kappa N^2.$$

Finally, we consider the third term on the r.h.s. of (2.5). To this end, we decompose the density Q_t in a sum over orthogonal projections

$$(2.10) \quad Q_t = \sum_{j=1}^N |\psi_{j,t}\rangle \langle \psi_{j,t}| \quad \text{with} \quad \langle \psi_{j,t}, \psi_{i,t} \rangle = \delta_{ij}.$$

It is easy to see that the wave functions $\{\psi_{j,t}\}_{j=1}^N$ are actually the solution of the Hartree-Fock system (1.3) with initial data $\{\psi_j\}_{j=1}^N$ chosen so that, at time $t = 0$, $\langle \psi_i, \psi_j \rangle = \delta_{ij}$ and $Q = \sum_{j=1}^N |\psi_j\rangle \langle \psi_j|$ (it is then easy to show that the r.h.s. of (2.10) is a solution to (1.5); from the local uniqueness of the solution to (1.5), we obtain (2.10)). Using this decomposition of the density Q_t , we obtain

$$(2.11) \quad \begin{aligned} & \operatorname{tr} \left[x\sqrt{p^2 + m^2} x, R_{Q_t} \right] Q_t \\ &= \sum_{j=1}^N \langle \psi_{j,t}, \left(\sqrt{p^2 + m^2} x^2 R_{Q_t} - R_{Q_t} x^2 \sqrt{p^2 + m^2} \right) \psi_{j,t} \rangle \\ &+ i \sum_{j=1}^N \langle \psi_{j,t}, \left(\frac{p}{\sqrt{p^2 + m^2}} \cdot x R_{Q_t} + R_{Q_t} x \cdot \frac{p}{\sqrt{p^2 + m^2}} \right) \psi_{j,t} \rangle \\ &= \sum_{i,j=1}^N \left\langle \psi_{j,t}, \left[\sqrt{p^2 + m^2}, x^2 \left(\frac{1}{|\cdot|} * \psi_{j,t} \bar{\psi}_{i,t} \right) \right] \psi_{i,t} \right\rangle \\ &+ i \operatorname{Re} \sum_{i,j=1}^N \left\langle \psi_{j,t}, \frac{p}{\sqrt{p^2 + m^2}} \cdot x \left(\frac{1}{|\cdot|} * \psi_{j,t} \bar{\psi}_{i,t} \right) \psi_{i,t} \right\rangle. \end{aligned}$$

To bound the last term on the r.h.s. of the last equation, we observe that

$$\begin{aligned} & \left| \sum_{i,j=1}^N \left\langle \psi_{j,t}, \frac{p}{\sqrt{p^2 + m^2}} \cdot x \left(\frac{1}{|\cdot|} * \psi_{j,t} \bar{\psi}_{i,t} \right) \psi_{i,t} \right\rangle \right| \\ & \leq \sum_{i,j=1}^N \int dx dy \left| \frac{p}{\sqrt{p^2 + m^2}} \psi_{j,t}(x) \right| |\psi_{i,t}(x)| |x| \frac{|\psi_{j,t}(y)| |\psi_{i,t}(y)|}{|x-y|} \\ & \leq \int dx dy \rho_{Q_t}(x) |x| \frac{\rho_{Q_t}(y)}{|x-y|} + \sum_j \int dx dy \left| \frac{p}{\sqrt{p^2 + m^2}} \psi_{j,t}(x) \right|^2 |x| \frac{\rho_{Q_t}(y)}{|x-y|} \\ & \leq CN^2 \end{aligned}$$

where we used Newton's law (Lemma 2.2) to perform the y -integration, and then, in the second term, we estimated $\text{tr}(p/\sqrt{p^2 + m^2})Q_t(p/\sqrt{p^2 + m^2}) \leq \text{tr} Q_t = N$. As for the first term on the r.h.s. of (2.11), we can bound its absolute value using Lemma 2.4. We find

$$\begin{aligned}
 (2.12) \quad & \left| \sum_{i,j=1}^N \left\langle \psi_{j,t}, \left[\sqrt{p^2 + m^2}, x^2 \left(\frac{1}{|\cdot|} * \psi_{j,t} \bar{\psi}_{i,t} \right) \right] \psi_{i,t} \right\rangle \right| \\
 & \leq \sum_{i,j=1}^N \left\| \left[\sqrt{p^2 + m^2}, x^2 \left(\frac{1}{|\cdot|} * \psi_{j,t} \bar{\psi}_{i,t} \right) \right] \right\| \\
 & \leq \sum_{i,j=1}^N \left(\left\| x \left(\frac{1}{|\cdot|} * \psi_{j,t} \bar{\psi}_{i,t} \right) \right\| + \left\| x^2 \nabla \left(\frac{1}{|\cdot|} * \psi_{j,t} \bar{\psi}_{i,t} \right) \right\| \right).
 \end{aligned}$$

To bound the first contribution, we observe that, by Lemma 2.2,

$$\begin{aligned}
 (2.13) \quad & \left\| x \left(\frac{1}{|\cdot|} * \psi_{j,t} \bar{\psi}_{i,t} \right) \right\| = \sup_x |x| \left| \int dy \frac{1}{|x-y|} \psi_{j,t}(y) \bar{\psi}_{i,t}(y) \right| \\
 & \leq \sup_x |x| \int dy \frac{1}{|x-y|} \frac{|\psi_{j,t}(y)|^2 + |\psi_{i,t}(y)|^2}{2} \\
 & \leq \sup_x |x| \int dy \frac{\rho_{Q_t}(y)}{|x-y|} \leq CN.
 \end{aligned}$$

Next, we consider the second term on the r.h.s. of (2.12). For $x \in \mathbb{R}^3$, we can find a rotation $R \in SO(3)$ such that $x = R(re_3)$ where $r = |x|$ and $e_3 = (0, 0, 1)$. Therefore

$$\begin{aligned}
 (2.14) \quad & |x|^2 \left| \int dy \frac{(x-y)}{|x-y|^3} \psi_{j,t}(y) \bar{\psi}_{i,t}(y) \right| = \left| r^2 \int dy \frac{(R(re_3)-y)}{|R(re_3)-y|^3} \psi_{j,t}(y) \bar{\psi}_{i,t}(y) \right| \\
 & \leq \sum_{i=1}^2 \left| r^2 \int dy \frac{y_i}{|re_3-y|^3} \psi_{j,t}(Ry) \bar{\psi}_{i,t}(Ry) \right| \\
 & \quad + \left| r^2 \int dy \frac{r-y_3}{|re_3-y|^3} \psi_{j,t}(Ry) \bar{\psi}_{i,t}(Ry) \right|.
 \end{aligned}$$

The last term on the r.h.s. of (2.14) can be estimated by

$$\begin{aligned}
 (2.15) \quad & \left| r^2 \int dy \frac{r-y_3}{|re_3-y|^3} \psi_{j,t}(Ry) \bar{\psi}_{i,t}(Ry) \right| \leq r^2 \int dy \frac{|r-y_3|}{|re_3-y|^3} |\psi_{j,t}(Ry)| |\psi_{i,t}(Ry)| \\
 & \leq r^2 \int dy \frac{|r-y_3|}{|re_3-y|^3} \rho_t(Ry) \\
 & \leq r^2 \int dy \frac{|r-y_3|}{|r-y|^3} \rho_t(y)
 \end{aligned}$$

Introducing spherical coordinates for $y = s\hat{y}$ for $\hat{y} \in S^2$, we find

$$\begin{aligned}
 (2.16) \quad & \left| r^2 \int dy \frac{r-y_3}{|re_3-y|^3} \psi_{j,t}(sy) \bar{\psi}_{i,t}(sy) \right| \leq \int_0^\infty ds s^2 \rho_t(s) \int_{S^2} d\hat{y} \frac{\left| 1 - \frac{s\hat{y}_3}{r} \right|}{\left| e_3 - \frac{s\hat{y}}{r} \right|} \leq CN.
 \end{aligned}$$

Here we used the fact that, as we prove in Lemma 2.5 below,

$$(2.17) \quad \sup_{\lambda > 0} \int_{S^2} d\hat{y} \frac{|1 - \lambda \hat{y}_3|}{|e_3 - \lambda \hat{y}|} < \infty.$$

As for the first term on the r.h.s. of (2.14), we remark that, for example, the summand with $i = 1$ can be controlled as follows.

$$(2.18) \quad \left| r^2 \int dy \frac{y_1}{|re_3 - y|^3} \psi_{j,t}(Ry) \bar{\psi}_{i,t}(Ry) \right| \leq \left| r \int dy \frac{(r - y_3)y_1}{|re_3 - y|^3} \psi_{j,t}(Ry) \bar{\psi}_{i,t}(Ry) \right| \\ + \left| r \int dy y_3 \frac{y_1}{|re_3 - y|^3} \psi_{j,t}(Ry) \bar{\psi}_{i,t}(Ry) \right|.$$

Observing that

$$\left| r \int dy y_3 \frac{y_1}{|re_3 - y|^3} \psi_{j,t}(Ry) \bar{\psi}_{i,t}(Ry) \right| \\ = \left| r \int dy y_3 \partial_{y_1} \frac{1}{|re_3 - y|} \psi_{j,t}(Ry) \bar{\psi}_{i,t}(Ry) \right| \\ \leq \left| r \int dy (y_3 \partial_{y_1} - y_1 \partial_{y_3}) \frac{1}{|re_3 - y|} \psi_{j,t}(Ry) \bar{\psi}_{i,t}(Ry) \right| \\ + r \int dy |y_1| \frac{|r - y_3|}{|re_3 - y|^3} |\psi_{j,t}(Ry)| |\psi_{i,t}(Ry)|$$

it follows from (2.18) that (using the notation $\varphi_{j,t}(y) = \psi_{j,t}(Ry)$)

$$(2.19) \quad \left| r^2 \int dy \frac{y_1}{|re_3 - y|^3} \psi_{j,t}(Ry) \bar{\psi}_{i,t}(Ry) \right| \\ \leq \left| r \int dy \frac{1}{|re_3 - y|} (L_2 \varphi_{j,t})(y) \bar{\varphi}_{i,t}(y) \right| + \left| r \int dy \frac{1}{|re_3 - y|} (L_2 \bar{\varphi}_{i,t})(y) \varphi_{j,t}(y) \right| \\ + r \int dy \frac{1}{|re_3 - y|^3} |\psi_{j,t}(Ry)| |\psi_{i,t}(Ry)| \\ \leq r \int dy \frac{1}{|re_3 - y|} (|L_2 \varphi_{j,t}(y)| |\varphi_{i,t}(y)| + |L_2 \varphi_{i,t}(y)| |\varphi_{j,t}(y)|) + r \int dy \frac{\rho_t(y)}{|re_3 - y|^3}.$$

The last term is bounded by CN by Lemma 2.2. The first term on the r.h.s. of the last equation, can be controlled by

$$(2.20) \quad r \int dy \frac{1}{|re_3 - y|} (|L_2 \varphi_{j,t}(y)| |\varphi_{i,t}(y)| + |L_2 \varphi_{i,t}(y)| |\varphi_{j,t}(y)|) \\ \leq r \sum_{j=1}^N \int dy \frac{1}{|re_3 - y|} (|L_2 \varphi_{j,t}(y)|^2 + |\varphi_{j,t}(y)|^2).$$

Note that $\sum_{j=1}^N |\varphi_{j,t}(y)|^2 = \rho_{Q_t}(Ry) = \rho_{Q_t}(y)$. Moreover, we have

$$\sum_{j=1}^N |L_2 \varphi_{j,t}(y)|^2 = \sum_{j=1}^N (L_2 |\varphi_{j,t}\rangle \langle \varphi_{j,t}| L_2)(y, y) = (L_2 \tilde{Q}_t L_2)(y, y)$$

where we defined $\tilde{Q}_t = \sum_j |\varphi_{j,t}\rangle\langle\varphi_{j,t}|$. Since

$$\tilde{Q}_t(x, y) = \sum_j \varphi_{j,t}(x) \bar{\varphi}_{j,t}(y) = \sum_j \psi_{j,t}(Rx) \bar{\psi}_{j,t}(Ry) = Q_t(Rx, Ry) = Q_t(x, y)$$

for all $x, y \in \mathbb{R}^3$, it follows that $\tilde{Q}_t = Q_t$. Therefore, from (2.19) and (2.20) we conclude that

$$\begin{aligned} \left| r^2 \int dy \frac{y_1}{|re_3 - y|^3} \psi_{j,t}(Ry) \bar{\psi}_{i,t}(Ry) \right| &\leq CN + r \int dy \frac{1}{|re_3 - y|} (L_2 Q_t L_2)(y, y) \\ &\leq CN + \sum_{\ell=1}^3 r \int dy \frac{1}{|re_3 - y|} (L_\ell Q_t L_\ell)(y, y). \end{aligned}$$

Since $\sum_{\ell=1}^3 (L_\ell Q_t L_\ell)(y, y)$ is invariant w.r.t. rotations of y , we can apply Lemma 2.2 to obtain that

$$\begin{aligned} \left| r^2 \int dy \frac{y_1}{|re_3 - y|^3} \psi_{j,t}(Ry) \bar{\psi}_{i,t}(Ry) \right| &\leq CN + C \sum_{\ell=1}^3 \int dy (L_\ell Q_t L_\ell)(y, y) \\ &= CN + C \operatorname{tr} L^2 Q_t. \end{aligned}$$

Using Lemma 2.3 and inserting the last bound and (2.16) back in (2.14) we find that

$$|x|^2 \left| \int dy \frac{(x-y)}{|x-y|^3} \psi_{j,t}(y) \bar{\psi}_{i,t}(y) \right| \leq CN + C \operatorname{tr} L^2 Q$$

and thus, from (2.12), that

$$\left| \sum_{i,j=1}^N \left\langle \psi_{j,t}, \left[\sqrt{p^2 + m^2}, x^2 \left(\frac{1}{|\cdot|} * \psi_{j,t} \bar{\psi}_{i,t} \right) \right] \psi_{i,t} \right\rangle \right| \leq CN^3(Q) + CN^2(Q) \mathcal{L}^2(Q)$$

From (2.5), we obtain (2.4).

Step 2. If Q_t is a solution of the Hartree-Fock equation (1.5), we have

$$(2.21) \quad \frac{d}{dt} \operatorname{tr} (p \cdot x + x \cdot p) Q_t \leq 2 \mathcal{E}_{\text{HF}}(Q).$$

To show (2.21), we compute

$$\begin{aligned} (2.22) \quad &\frac{d}{dt} \operatorname{tr} (p \cdot x + x \cdot p) Q_t \\ &= -i \operatorname{tr} (p \cdot x + x \cdot p) \left[\sqrt{p^2 + m^2} - \kappa \left(\frac{1}{|\cdot|} * \rho_{Q_t} \right) + \kappa R_{Q_t}, Q_t \right] \\ &= -i \operatorname{tr} \left[(p \cdot x + x \cdot p), \sqrt{p^2 + m^2} - \kappa \left(\frac{1}{|\cdot|} * \rho_{Q_t} \right) + \kappa R_{Q_t} \right] Q_t. \end{aligned}$$

Now we observe that

$$(2.23) \quad -i \operatorname{tr} \left[(p \cdot x + x \cdot p), \sqrt{p^2 + m^2} \right] Q_t = 2 \operatorname{tr} \frac{p^2}{\sqrt{p^2 + m^2}} Q_t \leq 2 \operatorname{tr} \sqrt{p^2 + m^2} Q_t$$

and

$$\begin{aligned}
 (2.24) \quad i\kappa \operatorname{tr} \left[(p \cdot x + x \cdot p), \left(\frac{1}{|\cdot|} * \rho_{Q_t} \right) \right] Q_t &= 2\kappa \operatorname{tr} x \cdot \nabla \left(\frac{1}{|\cdot|} * \rho_{Q_t} \right) Q_t \\
 &= -2\kappa \int dx dy x \cdot \frac{(x-y)}{|x-y|^3} \rho_{Q_t}(y) \rho_{Q_t}(x) \\
 &= 2\kappa \int dx dy y \cdot \frac{(x-y)}{|x-y|^3} \rho_{Q_t}(y) \rho_{Q_t}(x) \\
 &= \kappa \int dx dy \frac{1}{|x-y|} \rho_{Q_t}(y) \rho_{Q_t}(x).
 \end{aligned}$$

As for the contribution to (2.22) from the term with R_{Q_t} , we have

$$\begin{aligned}
 (2.25) \quad -i\kappa \operatorname{tr} \left[(x \cdot p + p \cdot x), R_{Q_t} \right] Q_t &= -2i\kappa \operatorname{tr} [x \cdot p, R_{Q_t}] Q_t \\
 &= -2i\kappa \operatorname{tr} (x \cdot p R_{Q_t} Q_t - R_{Q_t} x \cdot p Q_t) \\
 &= -2\kappa \int dx dy \left(x \cdot \nabla_x \left(\frac{Q_t(x, y)}{|x-y|} \right) Q_t(y, x) - Q_t(y, x) x \cdot \nabla_x Q_t(x, y) \right) \\
 &= 2\kappa \int dx dy x \cdot \frac{x-y}{|x-y|^3} |Q_t(x, y)|^2 \\
 &= \kappa \int dx dy \frac{|Q_t(x, y)|^2}{|x-y|}.
 \end{aligned}$$

From (2.22), (2.23), (2.24), and (2.25), we obtain (2.21).

Step 3. If Q_t is a spherically symmetric solution to (1.5), there exists a constant C , only depending from $N(Q)$ and $\mathcal{L}^2(Q)$ such that

$$(2.26) \quad \operatorname{tr} MQ_t \leq t^2 \mathcal{E}_{\text{HF}}(Q) + t (\operatorname{tr} (x \cdot p + p \cdot x) Q + C) + \operatorname{tr} MQ.$$

Eq. (2.26) follows directly from the statements proven in Step 1 and Step 2, integrating twice over time.

Step 4. Conclusion of the proof. From the assumption (2.3) on the initial density Q , it follows immediately that

$$\operatorname{tr} MQ = \operatorname{tr} x \sqrt{p^2 + m^2} x Q \leq \operatorname{tr} (1 + x^4 + p^2) Q < \infty$$

and that

$$|\operatorname{tr} (x \cdot p + p \cdot x) Q| \leq \operatorname{tr} (x^2 + p^2) Q < \infty.$$

Thus, if $\mathcal{E}_{\text{HF}}(Q) < 0$, (2.26) contradicts, for t large enough, the non-negativity of the expectation $\operatorname{tr} MQ_t$. This implies immediately that the maximal existence time T for the local solution Q_t is finite. From the blow-up alternative (see Theorem 1), it follows that there exists $T < \infty$ with $\|Q_t\|_{\mathcal{H}^{1/2}} = \operatorname{tr} (1 - \Delta)^{1/2} Q_t \rightarrow \infty$ as $t \rightarrow T^-$. \square

In the proof of Theorem 2, we had to control commutators of the pseudo-differential operator $\sqrt{p^2 + m^2}$ with multiplication operators of the form $f(x)$ (see for example (2.12)). In this respect, it turns out that the Calderon-Zygmund theory of singular integrals is very useful.

Lemma 2.4. *Suppose $m > 0$, $p = -i\nabla$. Then, for every $f \in W^{1,\infty}(\mathbb{R}^3)$, we have*

$$(2.27) \quad \left\| \left[\sqrt{p^2 + m^2}, f(x) \right] \right\| \leq C \|\nabla f\|_\infty.$$

A proof of this lemma can be found in [8]; see in particular the Corollary on page 309. The statement of this corollary does not give an effective bound on the norm of the commutator. However, the corollary is based on Theorem 3, on page 294 of [8], whose proof provides the effective control we need (a remark in this sense can be found in the paragraph 3.3.5, on page 305 of [8]).

Finally, in the next lemma we give a proof of the bound (2.17).

Lemma 2.5. *We have*

$$(2.28) \quad \sup_{\lambda \geq 0} \int_{S^2} d\hat{y} \frac{|1 - \lambda \hat{y}_3|}{|e_3 - \lambda \hat{y}|^3} < \infty.$$

Proof. First, we observe that

$$(2.29) \quad \sup_{\lambda < 1/2, \lambda > 2} \int_{S^2} dy \frac{|1 - \lambda y_3|}{|e_3 - \lambda y|^3} \leq C$$

because, in this regime of λ , there is no singularity from the denominator. On the other hand, for arbitrary $\lambda \in [1/2, 2]$, we have

$$\begin{aligned} \int_{S^2} d\hat{y} \frac{|1 - \lambda \hat{y}_3|}{|e_3 - \lambda \hat{y}|^3} &= 2\pi \int_0^\pi d\theta \sin \theta \frac{|1 - \lambda \cos \theta|}{(\lambda^2 \sin^2 \theta + (1 - \lambda \cos \theta)^2)^{3/2}} \\ &= 2\pi \int_0^\pi d\theta \sin \theta \frac{|1 - \lambda \cos \theta|}{\left(\frac{\lambda^2 - 1}{2} + 1 - \lambda \cos \theta\right)^{3/2}} \\ &= \frac{2\pi}{\lambda} \int_{1-\lambda}^{1+\lambda} dz \frac{|z|}{\left(\frac{\lambda^2 - 1}{2} + z\right)^{3/2}} = \frac{2\pi}{\lambda} \int_0^{2\lambda} dx \frac{|x + (1 - \lambda)|}{\left(\frac{(\lambda - 1)^2}{2} + x\right)^{3/2}} \end{aligned}$$

Therefore

$$\begin{aligned} \int_{S^2} d\hat{y} \frac{|1 - \lambda \hat{y}_3|}{|e_3 - \lambda \hat{y}|^3} &\leq C \int_0^{2\lambda} dx \frac{|x|}{\left(\frac{(\lambda - 1)^2}{2} + x\right)^{3/2}} + C \int_0^{2\lambda} dx \frac{(1 - \lambda)}{\left(\frac{(\lambda - 1)^2}{2} + x\right)^{3/2}} \\ &\leq C \int_0^4 \frac{dx}{|x|^{1/2}} + C \int_0^\infty dx \frac{1}{(1 + x)^{3/2}} \leq C. \end{aligned}$$
